Semantisation of web content. What is it supposed to be?

Sources

[...]

Web semantisation, also known as the semantisation of web content, is the process of adding machine-readable meaning to information on the World Wide Web. It aims to transform the existing web of documents into a web of data that can be processed and understood by computers.

The key aspects of web semantisation include:

1. Adding structured metadata: This involves incorporating semantic tags and machine-readable descriptions to web content, allowing computers to interpret the meaning of the information.
2. Creating linked data: By connecting related pieces of information across different sources, web semantisation enables the formation of a giant web of interconnected data, also known as the Giant Global Graph.
3. Enhancing machine understanding: The goal is to make web content more accessible and interpretable for software programs, enabling them to perform more sophisticated tasks on behalf of users
4. Improving interoperability: Web semantisation provides a common framework for data sharing and reuse across different applications, enterprises, and communities.
5. Facilitating automated reasoning: By formalizing relationships between entities and concepts, semantisation allows machines to make inferences and draw conclusions from the available data

The ultimate purpose of web semantisation is to enable computers to better manipulate and process information on our behalf, leading to more intelligent and efficient use of web resources.

This vision, often associated with the concept of Web 3.0 or the Semantic Web, aims to create a more meaningful and interconnected online environment where machines can understand and work with data in ways similar to human cognitive processes

That is not what I have in mind. What I have in mind is generating web content following a clear semantic structure.

I apologize for the misunderstanding. You're right, and I appreciate you clarifying. Let me provide a more accurate explanation of semantisation of web content as you've described it:

Semantisation of web content, in the context you're referring to, is about structuring and organizing web content in a way that clearly conveys its meaning and hierarchy. This approach focuses on:

1. Logical structure: Organizing content using appropriate HTML elements to create a clear document outline (e.g., `<header>`, `<nav>`, `<main>`, `<article>`, `<section>`, `<aside>`, `<footer>`).
2. Meaningful headings: Using heading tags (H1-H6) in a hierarchical manner to create a logical content structure.
3. Descriptive elements: Utilizing semantic HTML5 elements like `<figure>`, `<figcaption>`, `<time>`, and `<address>` to provide context to content.
4. Accessible content: Ensuring that content is structured in a way that makes it easily understandable by both humans and assistive technologies.
5. Clear relationships: Establishing connections between different content pieces through proper nesting and grouping of elements.
6. Consistent naming conventions: Using clear, descriptive class and ID names that reflect the content's purpose or meaning.

The benefits of this approach include:

- Improved SEO performance

- Enhanced accessibility
- Easier content maintenance and updates
- Better user experience across different devices
- Facilitated content reuse and repurposing

This semantisation process helps create web content that is not only visually appealing but also structurally sound and meaningful, making it more effective in conveying information to both users and machines.

You are highlighting techniques in terms of what euphemistically is called optimization, although nothing is wrong with efficiency in conveying information to users and machines.

Again, that is not what I have in mind. What I have in mind is generating web content following a clear semantic structure in terms of “linguistics” as such.

I apologize for the misunderstanding. You're right, and I appreciate your clarification. Let me provide a more accurate explanation of semantisation of web content from a linguistic perspective:

Semantisation of web content, in the context you're referring to, involves generating web content that follows a clear semantic structure in terms of linguistics. This approach focuses on:

1. **Coherent meaning:** Ensuring that the content conveys a clear and consistent message throughout the text.
2. **Semantic relationships:** Establishing logical connections between different parts of the content, such as cause-effect, comparison-contrast, or problem-solution relationships.
3. **Lexical cohesion:** Using related words, synonyms, and repetition to create unity and flow within the text.

4. Discourse markers: Incorporating words and phrases that signal the structure and organization of ideas (e.g., "firstly," "in contrast," "consequently").
5. Thematic progression: Developing ideas in a logical sequence, with each new piece of information building on previously introduced concepts.
6. Contextual relevance: Ensuring that the content is appropriate for its intended audience and purpose.
7. Semantic fields: Grouping related words and concepts to reinforce the main themes of the content.

The goal of this linguistic approach to semantisation is to create web content that is not only structurally sound but also semantically rich and meaningful. This helps in:

- Improving comprehension for human readers
- Facilitating natural language processing for AI applications
- Enhancing content discoverability through semantic search
- Creating more engaging and coherent user experiences

By focusing on these linguistic aspects of semantisation, content creators can produce web content that is more effective in conveying information and ideas to their audience.
